### c. Dr. Kenneth J. Wynne (ONR-Chemistry)

### d. Brief (100-200 words) description of project

This is an interdisciplinary project focused on the fundamental chemistry, physics and materials science of conducting polymers in the context of novel electronic phenomena associated with this emerging class of materials. The research draws upon and utilizes a broad base: synthesis and characterization of new conducting polymers, processing directed toward the achievement of chain oriented and chain extended materials with a goal of achieving the intrinsic electronic and optical properties, and physical measurements directed at characterizing these electronic and optical properties and of identifying the basic physical mechanisms involved in these phenomena.

### e. Significant Results During Past Year

We reported visible light emission from Schottky diodes made from semiconducting polymers. Our results demonstrated that light emitting diodes can be fabricated by casting the polymer film from solution with no subsequent processing or heat treatment required. Electrical characterization reveals diode behavior with rectification ratios of 100,000. Electroluminescence quantum efficiencies (photons out per electrons in) of 1% have been achieved. The discovery of conducting polymer LEDs expands the possible applications for conducting polymers into the area of active light sources. Controlling the energy gap of the polymer, either through the judicious choice of the conjugated backbone structure or through side-chain functionalization, should make possible a variety of colors. Moreover, because of the processing advantages of semiconductors cast from solution, large active areas can be envisioned.

### f. Brief (100-200 words) summary of plans for next years work

Our recent success with light emitting diodes fabricated from semiconducting polymers has opened an entirely new direction for our research --- with many new questions. Specific areas of importance for next year's research include optimization of luminescence efficiency (how to minimize non-radiative recombination), the achievement of stable conjugated polymers which emit blue light, and the achievement of highly oriented thin films which emit polarized luminescence (the latter can then be used to fabricate LEDs emitting *polarized* light).

In the area of electrical properties, we have made significant progress in improving the quality of the materials (through orientation by means of polymer processing). To proceed to take advantage of this important progress, we initiated the reconstruction of our transport laboratory to extend our measurement capabilities. The experimental capabilities within our electrical transport laboratory now include the following:

- (i) Electrical conductivity as a function of temperature from 1K to 300°C. Measurements above room temperature are intended primarily for evaluation of thermal stability.
- (ii) High pressure capability (up to 20kbar).
- (iii) Magneto-resistance (as a function of temperature and pressure) in magnetic fields up to 60 kgauss.
- (iv) Hall effect (vs temperature and vs pressure)
- (v) Thermopower (vs temperature) as a function of magnetic field and as a function of pressure
- (vi) AC complex conductivity over the extended frequency range from dc to 1 GHz.

The purpose of the focus on the addition of the high pressure capability is to increase the interchain electronic transfer interaction. As a result of our work in the past few years, we know that interchain delocalization to form anisotropic three-dimensional metals is of major importance. "Three-dimensionality" is essential for the achievement of high conductivities (for otherwise the mean free paths are limited by the tendency of the electronic states in quasi-one-dimensional systems to be localized by disorder).

Graduate students: D. Braun, Kwanghee Lee

Postdoctoral Researchers: D. Moses, K. J. Ihn, Y. Cao, C. Zhang

**Part III. Research Highlight**

**Viewgraphs and explanatory text on following pages:**

## **Visible Light Emission from Semiconducting Polymer Diodes**

- . We have reported visible light emission from Schottky diodes made from semiconducting polymers.
- . Our results demonstrated that light emitting diodes can be fabricated by casting the polymer film from solution with no subsequent processing or heat treatment required.
- . Electrical characterization reveals diode behavior with rectification ratios of 100,000.
- . Electroluminescence quantum efficiencies (photons out per electrons in) of 1% have been achieved; the light emitted from these devices is bright and easily seen in a fully lighted room.
- . Turn-on below 5 Volts; compatible with digital electronics.

Prof. Paul Smith  
Prof. Fred Wudl

Structure of Polymer LED Device

Polymer LED Rectification Ratio vs Bias Voltage

Polymer LED Quantum Efficiency vs Bias Voltage

### Part III. Research Highlight:

- The discovery of conducting polymer LEDs expands the possible applications for conducting polymers into the area of active light sources.
- Controlling the energy gap of the polymer, either through the judicious choice of the conjugated backbone structure or through side-chain functionalization, should make possible a variety of colors.
- Because of the processing advantages of of semiconductors cast from solution, large active areas can be envisioned.
- LEDs fabricated from conducting polymers offer a number of potential advantages to future technology.

### Part III. Research Highlight

#### Paragraph of explanatory text

The light emitting diodes, LEDs, consist of a rectifying Indium contact on the front surface of a semiconducting polymer (MEH-PPV) film which is deposited by spin-casting onto a glass substrate, partially coated with a layer of indium/tin-oxide (ITO), the "ohmic" contact. The MEH-PPV films are prepared by spin-casting from tetrahydrofuran (THF) solution containing 1% MEH-PPV by weight. The resulting MEH-PPV films have uniform surfaces with thicknesses near 1200Å. Rectifying metal contacts are deposited on top of the polymer films by vacuum evaporation. The fabrication steps are shown schematically in the Figure.

Using these remarkably simple structure, diodes with rectification ratios of  $10^5$  have been achieved. Using low work function metals (such as Calcium) as the rectifying contact, LEDs with quantum efficiency (photons out to electrons in) of 1% have been achieved.
